

SOME THEOREMS ON THE RELATIVE STRENGTHS  
OF MANY-VALUED LOGICS

ROLF SCHOCK

In what follows, we adopt the definitions given in the author's papers 'On finitely many-valued logics' (*Logique et Analyse*, n° 25-26 1964) and 'On denumerably many-valued logics' (*Ibid.*). Also, 'm', 'n', and 'p' are used as metalinguistic variables; the first two are to range over all positive integers greater than 1 and 'p' over these integers and also  $\omega$ .

If  $k$  is a positive integer, then the  $k^{\text{th}}$  sentential constant = (the  $2k^{\text{th}}$  individual constant the  $2k^{\text{th}}$  1-place predicate). A formula  $f$  is  $p$ -satisfiable just in case there are a  $p$ -interpreter  $i$  and assigner in  $U_i$   $a$  such that  $\text{Int } i a (f) \neq O$ . Similarly,  $f$  is sententially  $p$ -satisfiable just in case there is a  $v$  in  $VT_p$  such that  $v(f) \neq O$ . Obviously,  $f$  is  $p$ -satisfiable just in case  $\sim f$  is not  $p$ -valid and sententially  $p$ -satisfiable just in case  $\sim f$  is not a  $p$ -tautology.

If  $s_1, \dots, s_n$  are formulas, then  $s_1 < s_2 = \sim \vdash (s_2 \rightarrow s_1)$  and  $s_1 < \dots < s_n = \langle \dots \langle (s_1 < s_2) \wedge \dots \rangle \wedge (s_{n-1} < s_n) \rangle$ . Obviously,

*Theorem 1.* If  $s_1, \dots, s_n$  are distinct sentential constants, then  $s_1 < \dots < s_n$  is (sententially) <sup>(1)</sup>  $p$ -satisfiable just in case  $n$  is not greater than  $p$ .

Hence,

*Theorem 2.* If  $n$  is smaller than  $p$ ,  $s_1, \dots, s_{n+1}$  are distinct sentential constants, and  $t = \sim (s_1 < \dots < s_{n+1})$ , then

- (1)  $t$  is  $n$ -valid and not  $p$ -valid;
- (2)  $t$  is an  $n$ -tautology and not a  $p$ -tautology;
- (3) for any  $d$  and  $e$ , if  $d$  is an  $n$ -valued logic and  $e$  is a  $p$ -valued logic, then  $t$  is a  $d$ -provable and not  $e$ -provable; and
- (4)  $t$  is  $n$ -provable, but not  $p$ -provable.

For assume the antecedent. (1) and (2) follow immediately from theorem 1 and (3) follows from (1). (4) follows from (2) and (1) via

<sup>(1)</sup> We enclose a word in parentheses in a theorem to indicate that the theorem holds whether or not the word is present. Thus, every such theorem is really two theorems.

the facts that every formula which is an  $n$ -tautology is  $n$ -provable and that every  $p$ -provable formula is  $p$ -valid.

In other words, as we increase the number of truth values, we lose provable formulas.

We say that a positive integer  $i$  divides a positive integer  $j$  just in case there is a positive integer  $k$  such that  $k$  multiplied by  $i = j$ .

*Theorem 3.* If  $m-1$  divides  $n-1$ , then, for any formula  $f$ ,

- (1)  $f$  is  $n$ -valid only if  $f$  is  $m$ -valid;
- (2)  $f$  is an  $n$ -tautology only if  $f$  is an  $m$ -tautology<sup>(\*)</sup>;
- (3) for any  $d$  and  $e$ , if  $d$  is an  $m$ -valued logic and  $e$  is an  $n$ -valued logic, then  $f$  is  $e$ -provable only if  $f$  is  $d$ -provable; and
- (4)  $f$  is  $n$ -provable only if  $f$  is  $m$ -provable.

For assume the antecedent. Hence, for some positive integer  $k$ ,  $k$  multiplied by  $(m-1) = n-1$ . Assume now that  $i$  is an  $m$ -interpreter and that  $v$  is  $VT_m$ . For any positive integer  $k$  and predicate  $q$ , let  $Sq =$  the  $k$ -term sequence  $s$  such that the range of  $s = \{i(q)\}$ . Let  $j =$  the  $n$ -interpreter such that  $j(c) = i(c)$  for any individual constant  $c$  and  $j(q) = (Sq) (1) \wedge \dots \wedge (Sq) (k)$  for any predicate  $q$ . Finally, let  $w =$  the  $w$  in  $VT_n$  such that, for any sententially atomic formula  $a$ ,  $w(a) = (k \text{ multiplied by } (the \ b \text{ such that } v(a) = b \text{ divided by } (m-1))) \text{ divided by } (k \text{ multiplied by } (m-1))$ . By an induction among the members of  $TF$ , it can be shown that, for any term or formula  $t$ , formula  $g$ , and assigner in  $U_j = U_i \ a, Int \ j \ a \ (t) = Int \ i \ a \ (t)$  and  $w(g) = v(g)$ . Hence, if  $f$  is  $n$ -valid, then  $f$  is  $i$ -true; and, if  $f$  is an  $n$ -tautology, then  $v(f) = 1$ . But then (1) and (2) hold. (3) and (4) follow immediately from (1) and (2) respectively.

Combining theorems 2 and 3 with the facts that a formula is  $n$ -valid if  $\omega$ -valid, an  $n$ -tautology if an  $\omega$ -tautology, and  $n$ -provable if  $\omega$ -provable, we have

*Theorem 4.* If  $m$  is smaller than  $p$  and either  $m-1$  divides  $p-1$  or  $p = \omega$ , then

- (1) the set of all  $p$ -valid formulas is a proper subset of the set of all  $m$ -valid formulas;
- (2) the set of all formulas which are  $p$ -tautologies is a proper subset of the set of all formulas which are  $m$ -tautologies;

(\*) This is a generalization of the third part of theorem 17 of J. ŁUKASIEWICZ's and A. TARSKI's 'Investigations into the sentential calculus' (in TARSKI's book *Logic, Semantics, Metamathematics*, Oxford, 1956).

(3) for any  $d$  and  $e$ , if  $d$  is an  $m$ -valued logic and  $e$  is a  $p$ -valued logic, then the set of all  $e$ -provable formulas is a proper subset of the set of all  $d$ -provable formulas; and

(4) the set of all  $p$ -provable formulas is a proper subset of the set of all  $m$ -provable formulas.

The question now arises if there are other conditions for the consequences of theorem 4 than that  $m-1$  divides  $p-1$  when  $p$  is finite. We shall see that the answer is no.

If  $f$  and  $g$  are formulas, then  $f+g = \sim f \rightarrow g$  and  $f\dot{+}g = \langle \sim \vdash (f+g) \wedge (f+g) \rangle \vee \langle \vdash (f \leftrightarrow \sim g) \wedge (f+g) \rangle \vee \langle \sim \vdash (f \leftrightarrow \sim g) \wedge \vdash (f+g) \wedge \sim (f+g) \rangle$ .

Notice that, for any  $v$  in  $VTp$ ,  $v(f+g) = v(f\dot{+}g) = v(f) + v(g)$  when this sum is not greater than 1. On the other hand, when  $v(f) + v(g)$  is greater than 1,  $v(f+g) = 1$  while  $v(f\dot{+}g) = 0$ . A corresponding situation holds with respect to  $p$ -interpreters.

If  $f$  is a formula,  $k$  is a positive integer,  $s$  is a  $k$ -term sequence, and the range of  $s = \{f\}$ , then  $k \cdot f = (\dots(s(1) \dot{+} s(2)) \dot{+} \dots) \dot{+} s(k)$ . Notice that, for any  $v$  in  $VTp$ ,  $v(k \cdot f) = k$  multiplied by  $v(f)$  if this product is not greater than 1 and 0 otherwise. A corresponding situation holds with respect to  $p$ -interpreters. Now,

*Theorem 5.* If  $s$  is a sentential constant, then  $\vdash (m-1) \cdot s$  is (sententially)  $n$ -satisfiable just in case  $m-1$  divides  $n-1$ .

For assume the antecedent. If  $v$  is in  $VTn$ ,  $v(\vdash (m-1) \cdot s) \neq 0$ , and  $k =$  the natural number  $k$  such that  $v(s) = k$  divided by  $(n-1)$ , then  $(m-1)$  multiplied by  $(k$  divided by  $(n-1)) = 1$ ; that is,  $k$  multiplied by  $(m-1) = n-1$ . Hence,  $k \neq 0$  and so  $m-1$  divides  $n-1$ . Similarly, if  $k$  is a positive integer and  $k$  multiplied by  $(m-1) = n-1$ , then  $(m-1)$  multiplied by  $(k$  divided by  $(n-1)) = 1$ . But there is a  $v$  in  $VTn$  such that  $v(s) = k$  divided by  $(n-1)$  and so  $v(\vdash (m-1) \cdot s) = 1$ . Hence,  $\vdash (m-1) \cdot s$  is sententially  $n$ -satisfiable just in case  $m-1$  divides  $n-1$ . The proof with respect to  $n$ -satisfiability is analogous.

Hence,

*Theorem 6.* If  $m$  is smaller than  $n$ ,  $m-1$  does not divide  $n-1$ ,  $s$  is a sentential constant, and  $t = \sim \vdash (m-1) \cdot s$ , then

- (1)  $t$  is  $n$ -valid and not  $m$ -valid;
- (2)  $t$  is an  $n$ -tautology and not an  $m$ -tautology;
- (3) for any  $d$  and  $e$ , if  $d$  is an  $m$ -valued logic and  $e$  is an  $n$ -valued logic, then  $t$  is  $e$ -provable and not  $d$ -provable; and

(4)  $t$  is  $n$ -provable, but not  $m$ -provable.

For assume, the antecedent. (1) and (2) follow from theorem 5 and the fact that  $m-1$  divides  $n-1$  and (3) follows from (1). (4) follows from (2) and (1) via the facts that every formula which is an  $n$ -tautology is  $n$ -provable and that every  $m$ -provable formula is  $m$ -valid.

Combining theorems 4 and 6, we obtain

*Theorem 7.* If  $m$  is smaller than  $n$ , then the following conditions are equivalent:

- (1)  $m-1$  divides  $n-1$ ;
- (2) the set of all  $n$ -valid formulas is a (proper) subset of the set of all  $m$ -valid formulas;
- (3) the set of all formulas which are  $n$ -tautologies is a (proper) subset of the set of all formulas which are  $m$ -tautologies<sup>(3)</sup>;
- (4) for any  $d$  and  $e$ , if  $d$  is an  $m$ -valued logic and  $e$  is an  $n$ -valued logic, then the set of all  $e$ -provable formulas is a (proper) subset of the set of all  $d$ -provable formulas; and
- (5) the set of all  $n$ -provable formulas is a (proper) subset of the set of all  $m$ -provable formulas.
